

### 1.1 Normal Modes of Vibration

$$[M]\{\ddot{q}\} + [K]\{q\} = \{f(t)\} \rightarrow \{q(t)\} = \{C\} f(t) \rightarrow ([K] - \omega^2[M])\{C\} = \{0\} \quad (*)$$

Then, we derive an eigenvalue problem. This is the requirement for synchronous oscillations of the system. To compute  $\omega$  and  $\{C\}$  we consider the set of linear homogeneous equations  $(*)$  and require that  $\det([K] - \omega^2[M]) = 0$  in order to get non-trivial solutions for  $\{C\}$ .

$n$  eigenfrequencies squared  
 $0 < \omega_1^2 \leq \omega_2^2 \leq \dots \leq \omega_n^2$

Note that since  $[K] = [K]^T$  and  $[M] = [M]^T$  (as a result of the principle of reciprocity) and also are positive semi-definite, and positive-definite, respectively, that means that  $\omega_i^2 \geq 0$ ,  $i=1, \dots, n$ . Moreover, all roots of  $(**)$  are real.

Note that it is possible that  $\omega_i^2 = \omega_j^2$  for some  $i, j \in [1, \dots, n]$  (this is especially true for systems with symmetry).

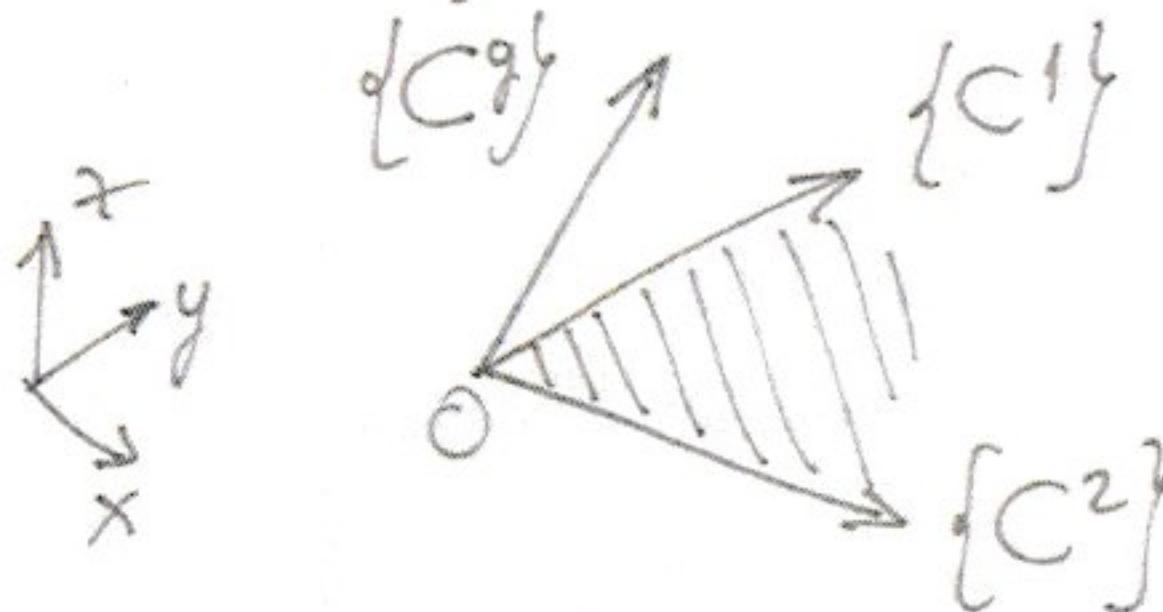

To each natural frequency squared  $\omega_r^2$  there corresponds a non-unique eigenvector computed by,

$$([K] - \omega_r^2[M])\{C\} = \{0\} \Rightarrow \text{Compute the eigenvector } \{C_r\} \text{ which is determined up to an arbitrary multiplicative constant}$$

How to evaluate the undetermined multiplicative constant? Many ways:

- Set one of the elements of  $\{C_r\}$  arbitrarily equal to 1
- Use mass-normalization, require that  $\{\bar{C}_r\}^T [M] \{C_r\} = 1$  Preferable for simplicity
- Require that the sum of the squares of all elements is equal to 1
- . . .

There are at most  $n$  linearly independent eigenvectors  $\{C_r\}, r=1, \dots, n$ ; although there are always  $n$  natural frequencies, the number of eigenvectors can be  $\leq n$  since there are degenerate cases where we have multiplicities of eigenfrequencies leading to a fewer number of "true eigenvectors". In cases like these we can define "generalized eigenvectors" to complete the basis of eigenvectors.

Denote the 'participation' of each mode in the response

Remarks This holds for distinct or repeated eigen-frequencies

i) The set of eigenvectors  $\{C_1, \dots, C_n\}$  is complete in the sense that any  $n$ -dimensional vector representing a possible oscillation of the system can be expressed as a linear superposition of the eigenvectors  $\Rightarrow$

$$\{q(t)\} = \alpha_1 \{C_1\} \cos(\omega_1 t + \phi_1) + \dots + \alpha_n \{C_n\} \cos(\omega_n t + \phi_n)$$

phase of each mode

The 'amplitudes'  $\alpha_i, i=1, \dots, n$  and the phases  $\varphi_i, i=1, \dots, n$  are then determined by the initial conditions.

ii) Orthogonality property of eigenvectors: Let's consider two eigenvectors corresponding to two distinct natural frequencies  $\omega_r$  and  $\omega_s \Rightarrow$  from (\*),

$$\begin{aligned} \omega_r^2 [M] \{C_r\} &= [K] \{C_r\} \Rightarrow \omega_r^2 \{C_s\}^T [M] \{C_r\} = \{C_s\}^T [K] \{C_r\} \\ \omega_s^2 [M] \{C_s\} &= [K] \{C_s\} \Rightarrow \omega_s^2 \{C_r\}^T [M] \{C_s\} = \{C_r\}^T [K] \{C_s\} \Rightarrow \\ &\Rightarrow \omega_s^2 \{C_s\}^T [M]^T \{C_r\} = \{C_s\}^T [K]^T \{C_r\} \Rightarrow \\ &\Rightarrow \omega_s^2 \{C_s\}^T [M] \{C_r\} = \{C_s\}^T [K] \{C_r\} \\ &\Rightarrow (\omega_r^2 - \omega_s^2) \{C_s\}^T [M] \{C_r\} = 0 \Rightarrow \end{aligned}$$

The modal matrix

$$\Rightarrow \boxed{\{C_s\}^T [M] \{C_r\} = 0}, r \neq s \quad \text{(Mass-orthogonality condition)}$$

But then, it also holds that  $\boxed{\{C_s\}^T [K] \{C_r\} = 0}, r \neq s$  (Stiffness-orthogonality condition)

But recall that one of the ways to normalize the eigenvectors was mass normalization, ie,  $\{C_r\}^T [M] \{C_r\} = 1, r=1, \dots, n \Rightarrow$  If we define the matrix of eigenvectors,

$$[C] = [\{C_1\}, \{C_2\}, \dots, \{C_n\}] \Rightarrow [C]^T [M] [C] = \boxed{I_n} \quad \text{(Identity matrix)} \quad \text{(orthonormalization wrt mass matrix)}$$

For the special matrix of eigenvectors that satisfies the mass orthogonality conditions (\*\*), we will reserve the table Mass-orthonormalized Modal Matrix  $[\Phi] \equiv [\Phi]$ ,  $[\Phi]^T [M] [\Phi] = [I]$ ,  $[\Phi]^T [K] [\Phi] = [\omega_r^2]$

Then, the original equations of motion assume a very nice form!

$$[M]\{\ddot{q}\} + [K]\{q\} = \{0\} \quad \Rightarrow \quad [M][\Phi]\{\ddot{\gamma}\} + [K][\Phi]\{\gamma\} = \{0\} \Rightarrow$$

$$\{\ddot{q}\} = [\Phi]\{\gamma\}$$

$\xrightarrow{\text{From generalized coordinates to modal coordinates}}$

$$\Rightarrow \underbrace{[\Phi]^T [M] [\Phi]}_{[I]} \{\ddot{\gamma}\} + \underbrace{[\Phi]^T [K] [\Phi]}_{[\omega_r^2]} \{\gamma\} = \{0\} \Rightarrow$$

$$\Rightarrow [I]\{\ddot{\gamma}\} + [\omega_r^2]\{\gamma\} = \{0\} \Rightarrow$$

$$\Rightarrow \ddot{\gamma}_r + \omega_r^2 \gamma_r = 0, r = 1, \dots, n$$

Initial conditions:

$$\{q(0)\} = [\Phi]\{\gamma(0)\} \Rightarrow$$

$$\Rightarrow \{\gamma(0)\} = [\Phi]^{-1}\{q(0)\}$$

$$\{\dot{\gamma}(0)\} = [\Phi]'\{q(0)\}$$

In terms of modal coordinates we get a set of uncoupled linear oscillators!

$$\gamma_r(t) = \alpha_r \cos(\omega_r t + \varphi_r) \Rightarrow$$

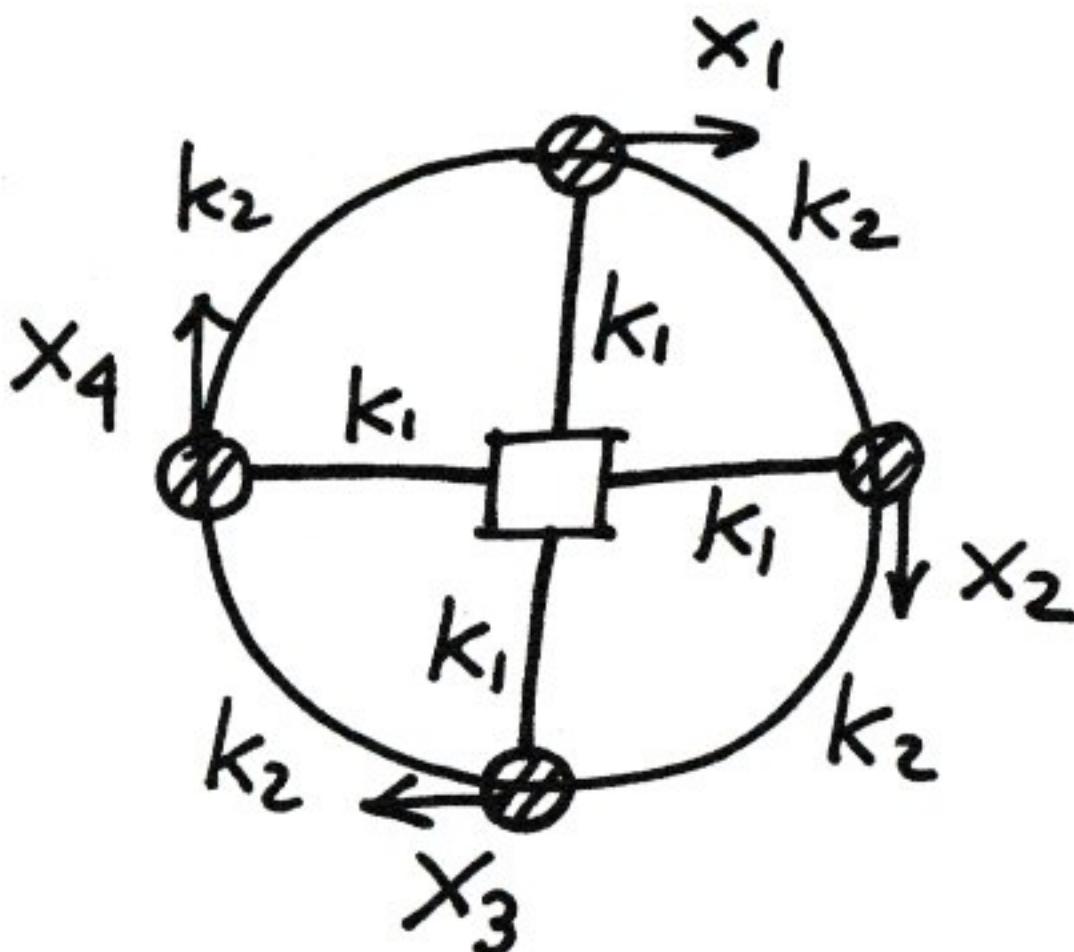

$$\Rightarrow \{q\} = [\Phi] \left\{ \begin{array}{l} \alpha_1 \cos(\omega_1 t + \varphi_1) \\ \vdots \\ \alpha_n \cos(\omega_n t + \varphi_n) \end{array} \right\} \Rightarrow$$

$$\Rightarrow \{q(t)\} = \sum_{r=1}^n \alpha_r \{\dot{\gamma}_r\} \cos(\omega_r t + \varphi_r), \alpha_r \text{ and } \varphi_r \text{ determined by initial conditions}$$

iii) Suppose  $\exists p$  repeated eigenfrequencies of an  $n$ -DOP linear system, where  $2 \leq p < n \Rightarrow$  Since  $[K]$  and  $[M]$  are symmetric square matrices we can always define a complete, orthogonal basis of eigenvectors. However, there are  $n-p$  uniquely defined eigenvectors (corresponding to the  $n-p$  distinct eigenfrequencies), and  $p$  non-unique eigenvectors that span an  $p$ -dimensional invariant modal subspace; any orthogonal base of that  $p$ -dim invariant subspace can be "generalized" eigenvectors of the system.

### Example

All masses  
are  
identical  
and  
normalized  
to unity

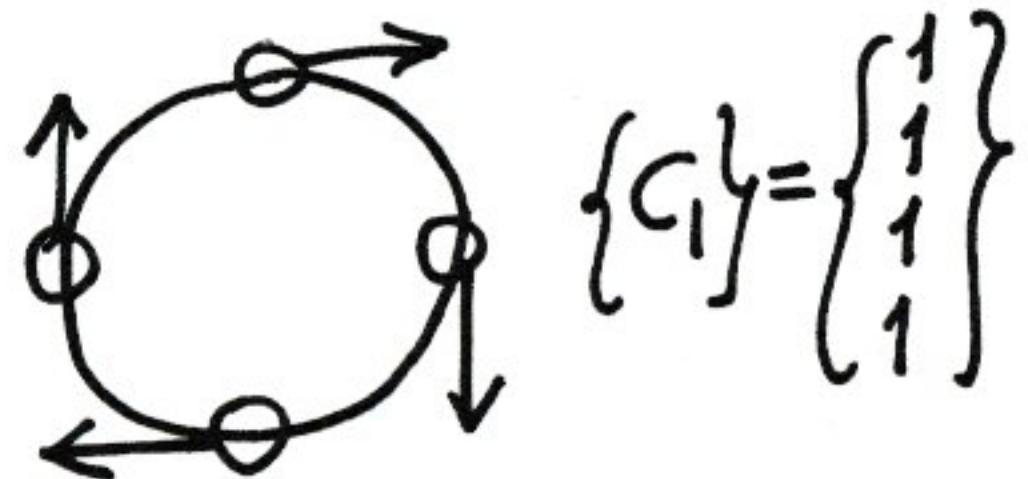

The equations of motion are given by:

$$\begin{Bmatrix} \ddot{x}_1 \\ \ddot{x}_2 \\ \ddot{x}_3 \\ \ddot{x}_4 \end{Bmatrix} + \begin{bmatrix} k_1+2k_2 & -k_2 & 0 & -k_2 \\ -k_2 & k_1+2k_2 & -k_2 & 0 \\ 0 & -k_2 & k_1+2k_2 & -k_2 \\ -k_2 & 0 & -k_2 & k_1+2k_2 \end{bmatrix} \begin{Bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{Bmatrix} = \begin{Bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{Bmatrix}$$

The symmetry of this system yields degeneracy of its vibration modes, with two repeated eigenfrequencies.

### Mode 1

(Unique eigen-vector)

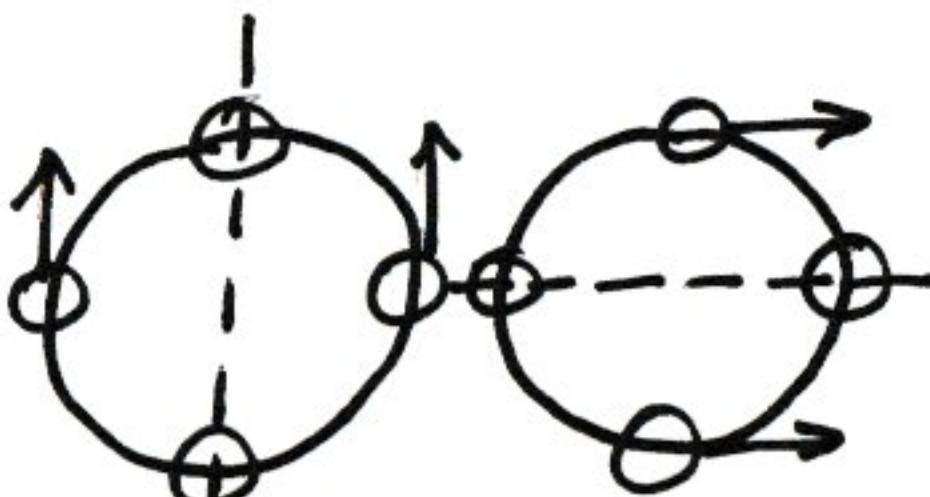

Nat. frequency  
 $\omega_1$

↑  
Represents a 1-dim invariant line in the configuration space  $(x_1, x_2, x_3, x_4)$ , or a 2-dim invariant subspace in the 8-dim phase space of the system.

$(\dot{x}_1, \ddot{x}_1, \dot{x}_2, \ddot{x}_2, \dot{x}_3, \ddot{x}_3, \dot{x}_4, \ddot{x}_4) \Rightarrow$  On this mode system behaves like a SDOF system.

### Mode 2,3

(Non-unique pairs of eigen-vectors)

Nat. frequencies  
 $\omega_2 = \omega_3$

$$\{C_2\} = \begin{bmatrix} 0 \\ 1 \\ 0 \\ -1 \end{bmatrix}, \{C_3\} = \begin{bmatrix} 1 \\ 0 \\ -1 \\ 0 \end{bmatrix}$$

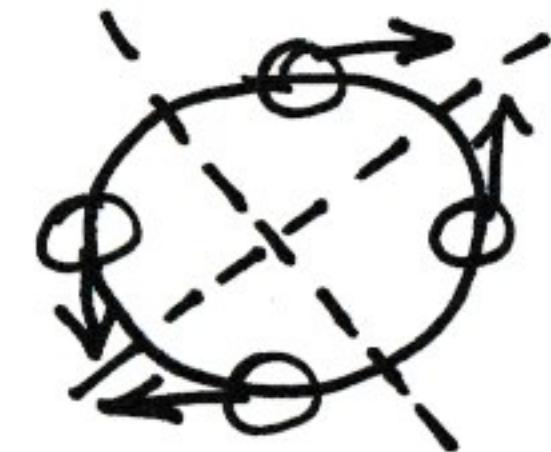

But  $\{C_{23}\} = \alpha_1 \{C_2\} + \beta_1 \{C_3\}$  is also an eigenvector,  $\alpha_1, \beta_1 \in \mathbb{R}$

↑  
These generalized eigenvectors span a 4-dimensional invariant modal subspace in the 8-dim phase space of the system.

### Mode 4

(Unique eigen-vector)

$$\{C_4\} = \begin{bmatrix} 1 \\ -1 \\ 1 \\ -1 \end{bmatrix}$$

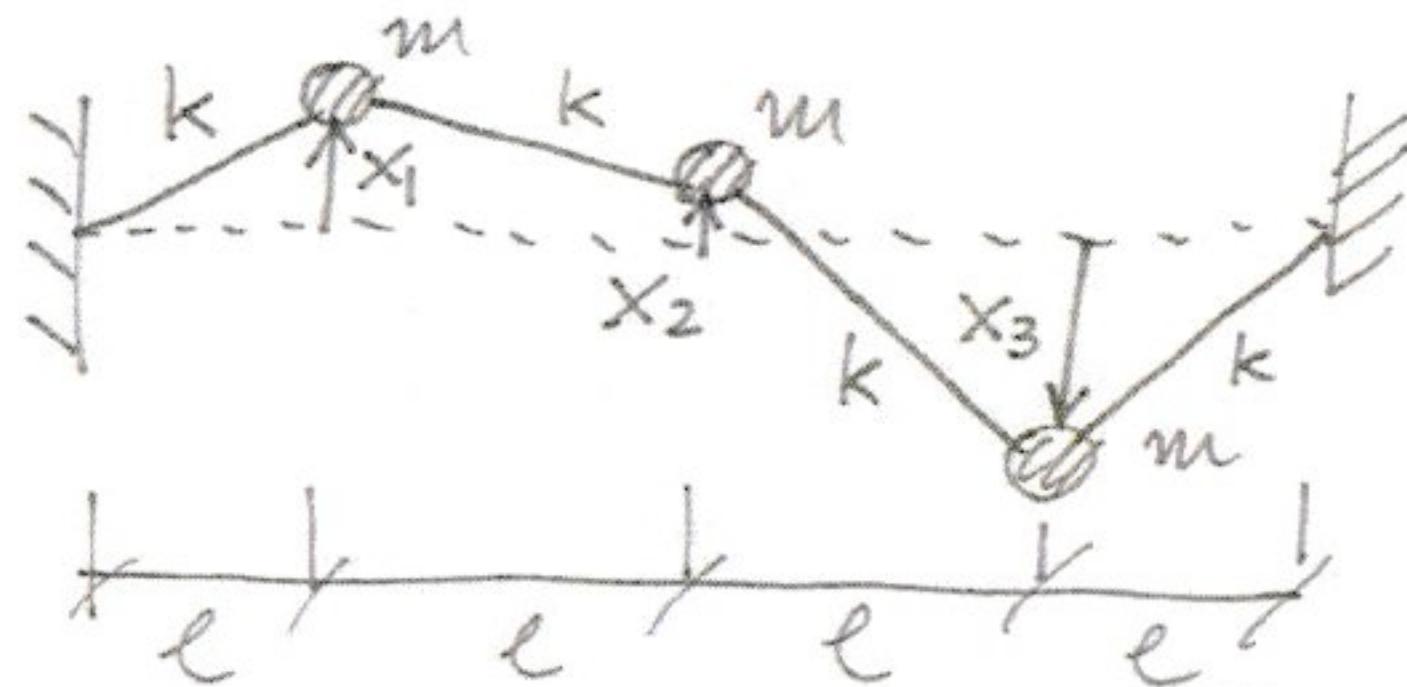

Nat. frequency  
 $\omega_4$

↑  
Spans a 2-dim invariant manifold in the 8-dim phase space  $\Rightarrow$  When the system oscillates in this mode it behaves like a SDOF linear oscillator.

Example

Small cluster

$$T = \frac{1}{2}m\dot{x}_1^2 + \frac{1}{2}m\dot{x}_2^2 + \frac{1}{2}m\dot{x}_3^2$$

$$V = \frac{1}{2}kx_1^2 + \frac{1}{2}k(x_1 - x_2)^2 + \frac{1}{2}k(x_2 - x_3)^2 + \frac{1}{2}kx_3^2$$

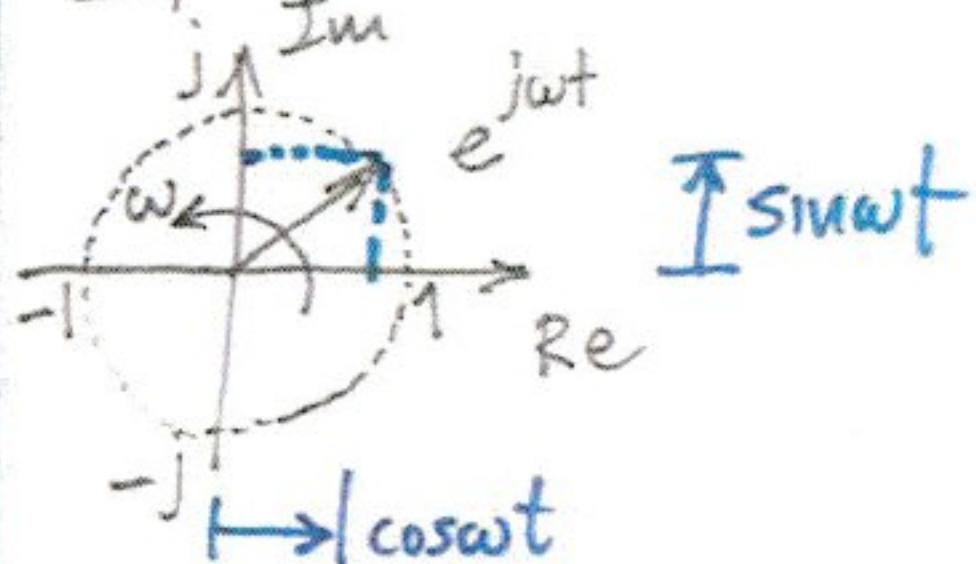

$k = T/e$ ,  $T$  = Internal constant tension in each elastic string.

Then,  $T = \frac{1}{2}\{\dot{x}\}^T \begin{bmatrix} m & 0 & 0 \\ 0 & m & 0 \\ 0 & 0 & m \end{bmatrix} \{\dot{x}\}$ ,  $V = \frac{1}{2}\{x\}^T \begin{bmatrix} 2k & -k & 0 \\ -k & 2k & -k \\ 0 & -k & 2k \end{bmatrix} \{x\}$ ,  $\{x\} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$

So, the equations of motion can be written as  $[M]\{\ddot{x}\} + [K]\{x\} = \{0\}$

To compute the natural modes of this system require that  $\{x\} = \{C\} e^{j\omega t}$ ,  $j = \sqrt{-1}$

Digression

$$e^{j\omega t} = \cos\omega t + j\sin\omega t$$

Now the usual notation for oscillating systems is real steady state,  $\varphi = \frac{\omega}{\eta}$  or  
 $m\ddot{x} + kx = F \cos\omega t \Rightarrow x(t) = A \cos(\omega t + \varphi)$  (real solution),  $\varphi = \frac{\omega}{\eta}$   
 $m\ddot{x} + kx = Fe^{j\omega t} \Rightarrow x(t) = X^* e^{j\omega t} = |X^*| e^{j\varphi} e^{j\omega t} = |X^*| e^{j(\omega t + \varphi)}$

Substituting into the equations of motion,

$$\{x\} = \{C\} e^{j\omega t} \Rightarrow \{\ddot{x}\} = -\omega^2 \{C\} e^{j\omega t} \Rightarrow -\omega^2 [M] \{C\} e^{j\omega t} + [K] \{C\} e^{j\omega t} = \{0\}$$

$$\Rightarrow ([K] - \omega^2 [M]) \{C\} e^{j\omega t} = \{0\} \Rightarrow \text{Eigenvalue problem} / ([K] - \omega^2 [M]) \{C\} = \{0\}$$

for this example,  $\underbrace{\begin{bmatrix} 2k-m\omega^2 & -k & 0 \\ -k & 2k-m\omega^2 & -k \\ 0 & -k & 2k-m\omega^2 \end{bmatrix}}_{[A]} \begin{bmatrix} C_1 \\ C_2 \\ C_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$

for nontrivial solutions we require that  $\det [A] = 0 \Rightarrow$

$$\Rightarrow J_1 \omega^6 + J_2 \omega^4 + J_3 \omega^2 + J_4 = 0 \Rightarrow \omega_1^2 < \omega_2^2 < \omega_3^2$$

Once  $\omega_r^2$  is computed,  $r=1,2,3$  we substitute back into the eigenvalue problem,

$$\left. \begin{aligned} (2k-m\omega_r^2) C_1 - k C_2 &= 0 \Rightarrow \frac{C_1}{C_2} = \frac{k}{2k-m\omega_r^2} \\ -k C_1 + (2k-m\omega_r^2) C_2 - k C_3 &= 0 \\ -k C_2 + (2k-m\omega_r^2) C_3 &= 0 \Rightarrow \frac{C_2}{C_3} = \frac{2k-m\omega_r^2}{k} \end{aligned} \right\} \Rightarrow \begin{aligned} C_2 &= \frac{(2k-m\omega_r^2)\lambda}{k} \\ C_3 &= \frac{(2k-m\omega_r^2)\lambda}{2k-m\omega_r^2} = \lambda \end{aligned}$$

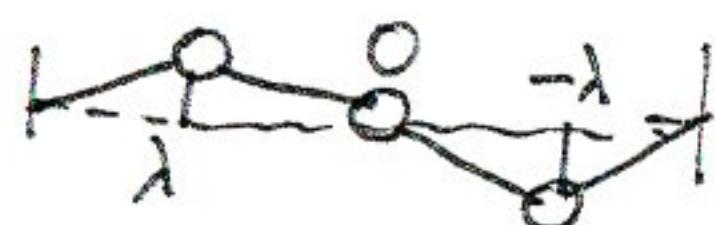

Let  $C_1 = \lambda$

Then,  $\begin{bmatrix} C_1 \\ C_2 \\ C_3 \end{bmatrix} = \begin{bmatrix} \lambda \\ \frac{(2k-m\omega_r^2)\lambda}{k} \\ \lambda \end{bmatrix}$  !  $\lambda$  is arbitrary multiplicative constant

Eigenvector 1

Corresponds to  $\omega_1^2$

Corresponds to  $\omega_2$

Corresponds to  $\omega_3^2$

#### iv) Geometric interpretation of normal modes.

Consider again the eigenvalue problem  $[K]\{C\} = \omega^2[M]\{C\} \Rightarrow$

$$\Rightarrow \underbrace{[M]^{-1}}_{[\alpha]} [K] \{C\} = \omega^2 \underbrace{[M]^{-1} [M]}_{I = [2]} \{C\} = \omega^2 \{C\} \Rightarrow [\alpha] \{C\} = \omega^2 \{C\} \quad \text{Let } \omega^2 = 1$$

$$\Rightarrow \{C\}^T [\alpha] \{C\} = 1 \quad \left. \begin{array}{l} \{C\}^T [\alpha] \{C\} = \lambda \\ \{C\}^T \{C\} = 1 \end{array} \right\} \Rightarrow \boxed{\{C\}^T [\alpha] \{C\} = \lambda} \quad \left. \begin{array}{l} \{C\}^T [\alpha] \{C\} = \lambda \\ \{C\}^T \{C\} = 1 \end{array} \right\} \Rightarrow$$

Let's normalize  $\{C\}$  so that  $\{C\}^T \{C\} = 1$

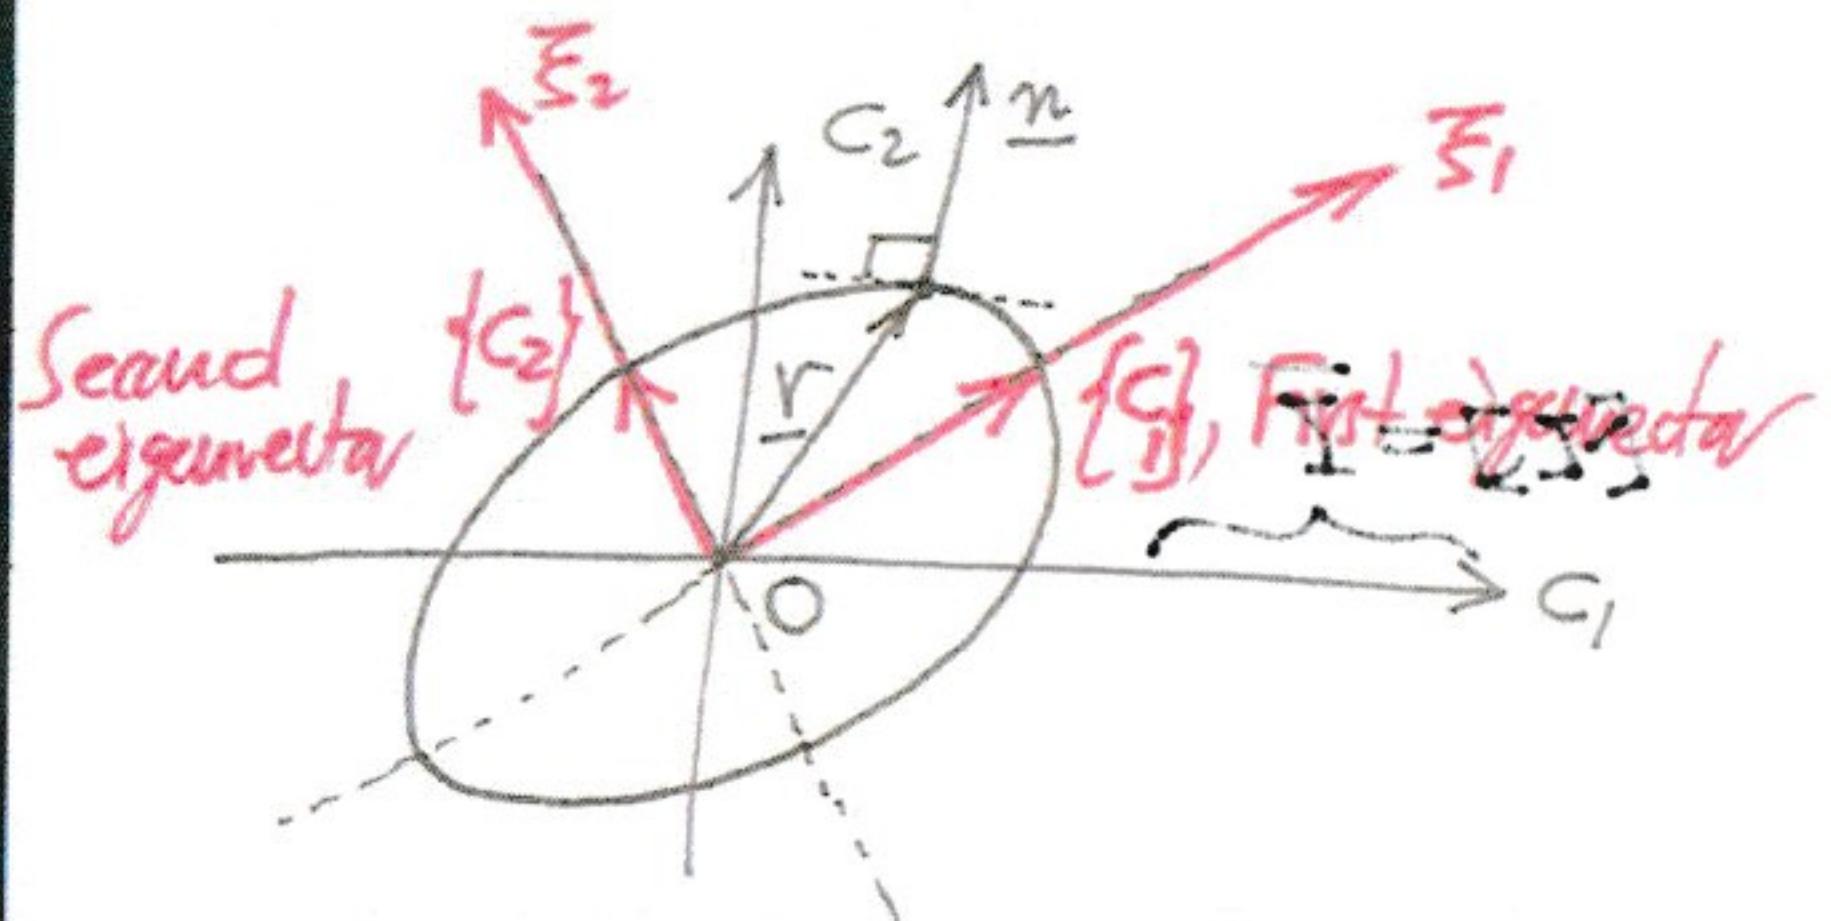

Assume that we have a two-degree-of-freedom system,  $\{C\} = \begin{pmatrix} c_1 \\ c_2 \end{pmatrix}$

$[\alpha] = \begin{bmatrix} \alpha_{11} & \alpha_{12} \\ \alpha_{21} & \alpha_{22} \end{bmatrix}$ , where  $\alpha_{12} = \alpha_{21}$  due to the symmetries of  $[M]$  and  $[K]$

$$\leftarrow \{C\} = \begin{pmatrix} C_1 \\ C_2 \end{pmatrix}$$

$$\frac{1}{\lambda} [\alpha_{11} c_1^2 + \underbrace{(\alpha_{12} + \alpha_{21})}_{2\alpha_{12}} c_1 c_2 + \alpha_{22} c_2^2] = 1 \Rightarrow \left\{ \underline{c} \right\} = \begin{Bmatrix} c_1 \\ c_2 \end{Bmatrix}$$

$$\Rightarrow \boxed{\frac{1}{\lambda} [\alpha_{11} c_1^2 + 2\alpha_{12} c_1 c_2 + \alpha_{22} c_2^2] = 1}$$

Eigenvalue problem is:

$$[\alpha] \{c\} = \lambda \{c\}$$

This is a conic section, which for vibrations of mechanical system is an ellipse. Note that the normal to the ellipse at any point is  $\underline{n} \sim [\alpha] \{c\} \Rightarrow$

The eigenvalue problem can be interpreted as the problem of finding  $\lambda$  such that the direction  $\underline{n} \sim \underline{v}$ ,

which the problem of finding the principal axes of the ellipse! In other words, it will be satisfied that

$$[\alpha] \{c\} \sim \lambda \{c\} \Rightarrow$$

$$\Rightarrow \{c\}^T [\alpha] \{c\} = \lambda \{c\}^T \{c\} = \lambda$$

Once these principal components are determined we may introduce new modal coordinates  $(\xi_1, \xi_2)$  in terms of which the ellipse is written in simplest form,  
 $\frac{1}{\lambda} b_{11} \xi_1^2 + \frac{1}{\lambda} b_{22} \xi_2^2 = 1$ ,

this is identical to setting  $\{C\} = [R]\{\tilde{F}\} \Rightarrow [\alpha][R]\{\tilde{F}\} = \lambda[R]\{\tilde{F}\}$

$$\Rightarrow \frac{1}{\lambda} \{F\}^T [R]^T [\alpha] [R] \{\tilde{F}\} = 1 \Rightarrow \underbrace{\frac{1}{\lambda} \{F\}^T [b_y] \{\tilde{F}\}}_{\text{rotation}} = 1 \quad \left. \begin{array}{l} \lambda_1 = b_{11}, \{F_1\} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \\ \text{But } \{F\}^T \{F\} = 1 \quad \lambda_2 = b_{22}, \{F_2\} = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \end{array} \right\}$$

These represent the two eigenvalues and the two eigenvectors of the system

### v) Forced response by modal analysis

It is easy to extend modal analysis to the forced case. Suppose that the original equations of motion are:

$$\begin{aligned} [M]\{\ddot{q}\} + [K]\{q\} &= \{F(t)\} \quad \Rightarrow \quad [M]\underbrace{[\Phi]\{\ddot{y}\}}_{\substack{\text{I} \\ \text{Orthonormalized modal}}} + [K]\underbrace{[\Phi]\{y\}}_{\substack{\text{matrix} \\ [\omega_r^2]}} = \{F(t)\} \Rightarrow \\ \text{Let } \{q\} &= \underbrace{[\Phi]\{y\}}_{\substack{\text{Orthonormalized modal} \\ \text{matrix}}} \quad \Rightarrow \quad [\Phi]^T [M] [\Phi] \{\ddot{y}\} + [\Phi]^T [K] [\Phi] \{y\} = \\ &= [\Phi]^T \{F(t)\} \Rightarrow \\ &\Rightarrow \{\ddot{y}\} + [\omega_r^2] \{y\} = \underbrace{[\Phi]^T \{F(t)\}}_{\{Q(t)\}} \Rightarrow \\ &\Rightarrow \ddot{y}_r + \omega_r^2 y_r = Q_r, \quad r=1, \dots, n \end{aligned}$$

Remark: If  $[M] = [I]$ ,  
then  $[\Phi]^T [\Phi] = [I] \Rightarrow$   
 $\Rightarrow [\Phi]^T = [\Phi]^{-1}$   
Then,  $[\Phi]$  is an  
orthogonal matrix.

Then we get an uncoupled set of forced modal oscillators, with each representing the forced response of an individual mode of vibration. So, each modal oscillator is solved independently of the others with initial conditions:

$$\{y(0)\} = [\Phi]^{-1}\{q(0)\}, \quad \{\dot{y}(0)\} = [\Phi]^{-1}\{\dot{q}(0)\}$$

# Role of Damping

Necessary + sufficient condition for proportional damping  $\rightarrow$  Theorem by T.K. Caughey  
 Sufficient condition  $[D] = \alpha [M] + \beta [K]$   
 $\alpha, \beta \in \mathbb{R}$

$$[M]\{\ddot{q}\} + [K]\{q\} + [D]\{\dot{q}\} = \{F(t)\}$$

Can we use modal analysis to solve this problem?

→ Can we use the same modal transformation  $\{q\} = [\Phi]\{y\}$  to  
 As far as the undamped problem  
 decouple the equations of motion?

$$[\Phi]^T [M] [\Phi] \{ \ddot{y} \} + [\Phi]^T [K] [\Phi] \{ y \} + \underbrace{[\Phi]^T [D] [\Phi] \{ \dot{y} \}}_{?} = \{ F(t) \}$$

$[\Phi]^T$

$\{ \ddot{y} \}$

$[\Phi]$

$\{ y \}$

$[\Phi]^T [D] [\Phi]$

Yes! we can use  
 the same modal matrix  
 to uncouple the damped  
 equations!

No, modal  
 analysis does  
 not work here.

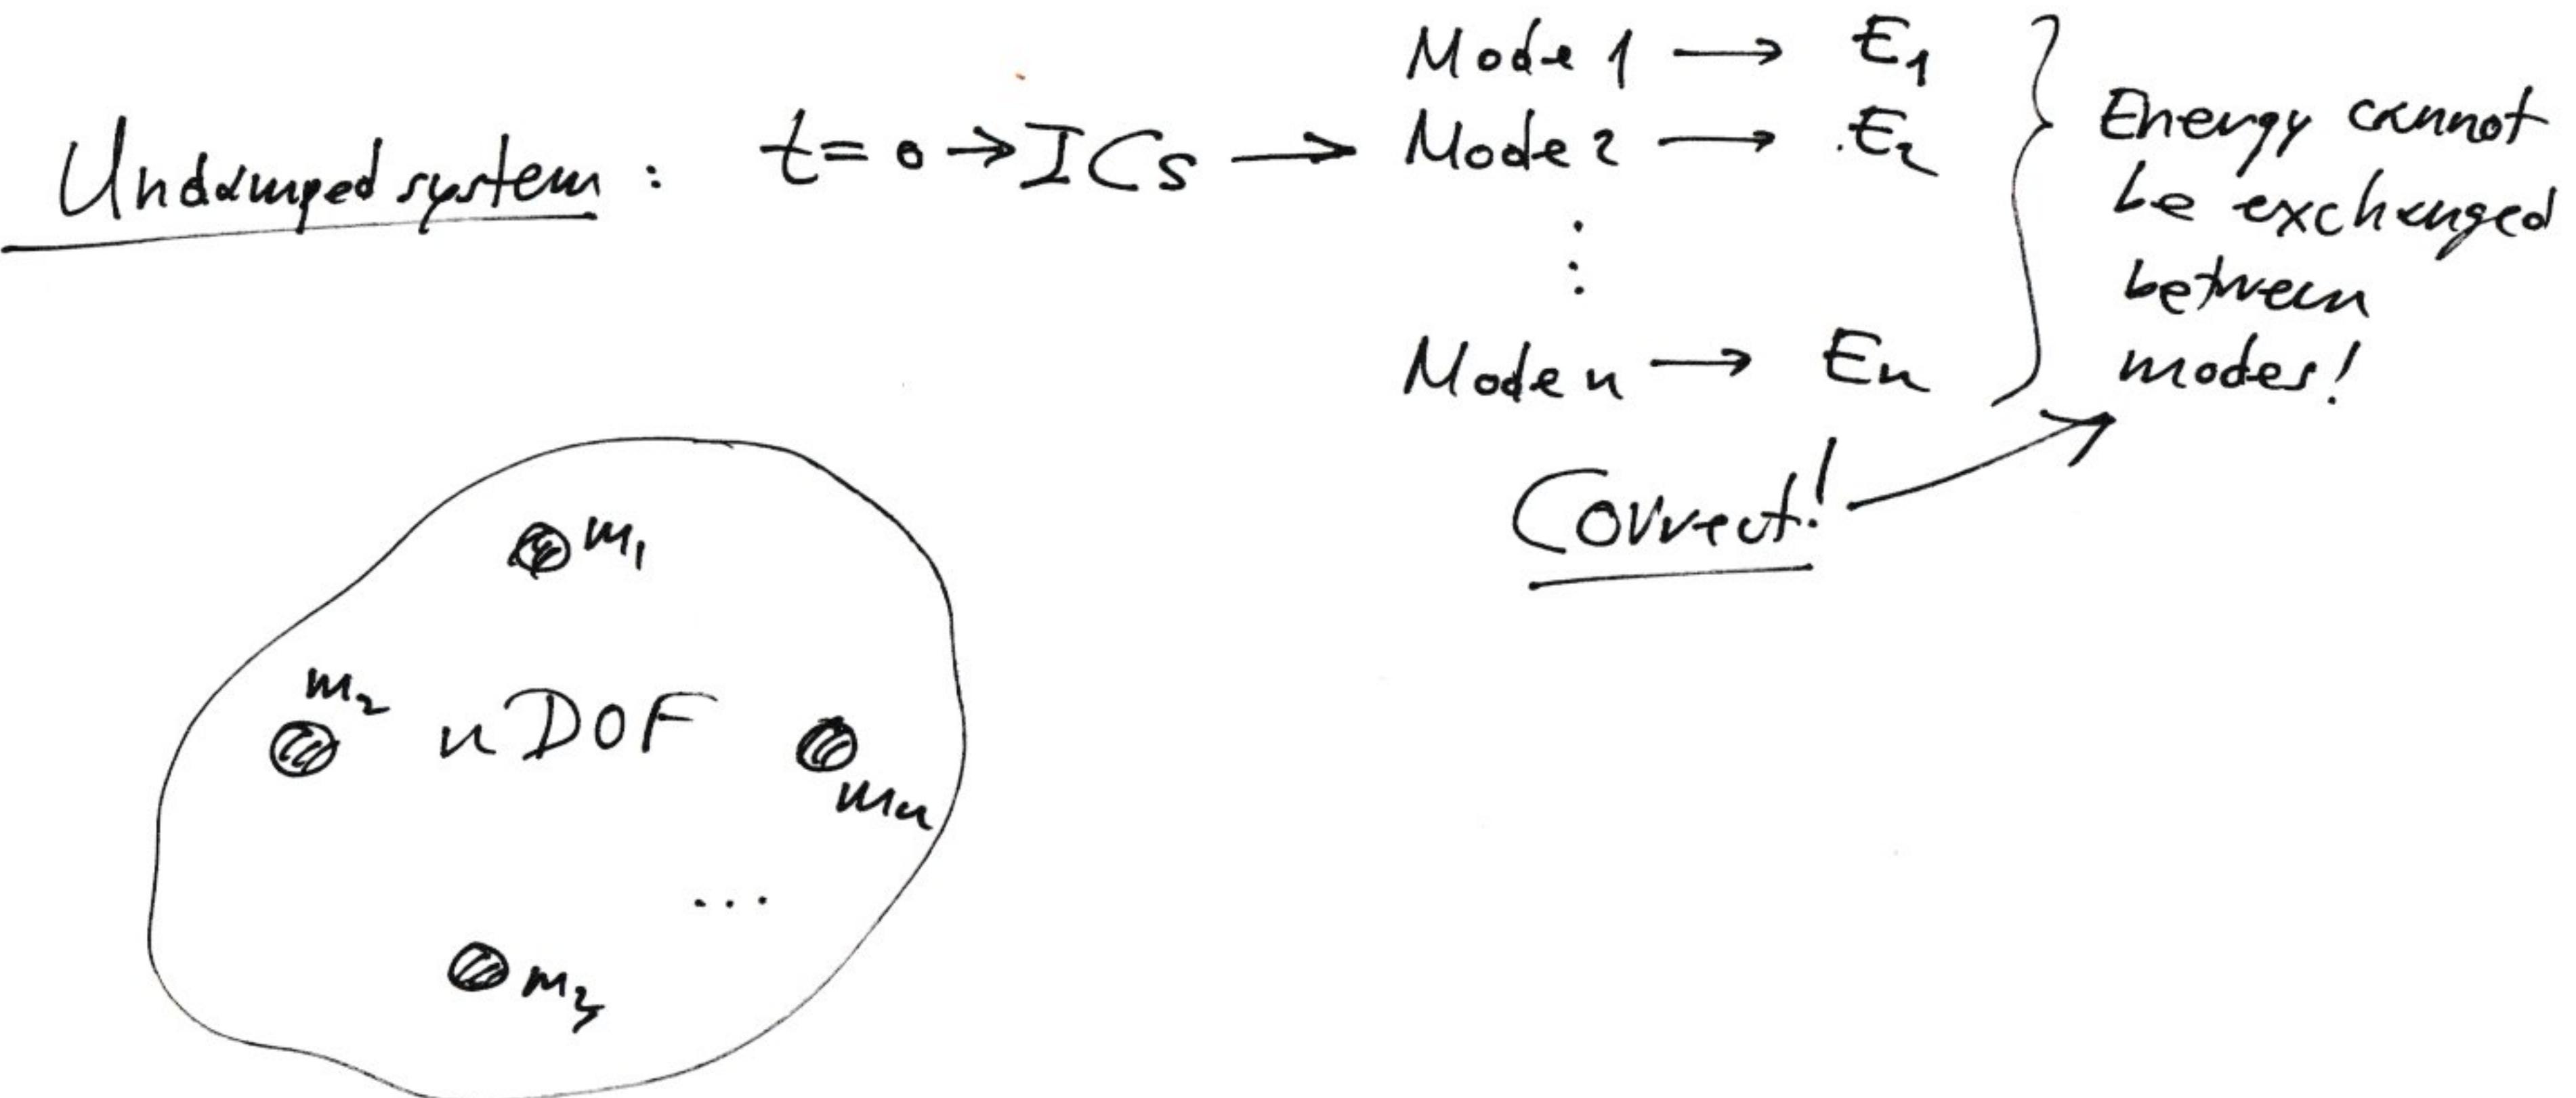

Either  $[\Phi]^T [D] [\Phi] = [\Theta]$

Proportional damping

or

$$[\Phi]^T [D] [\Phi] \neq [\Theta]$$

Non-proportional damping

Damped system:  $t=0 \rightarrow \text{ICs} \rightarrow$  Mode i gets initial energy  $E_i$ , this energy cannot be exchanged between modes!

(light)

Almost correct: Correct if damping distribution is proportional

Closely spaced modes with non-proportional damping do exchange energy between them!  $\Rightarrow$  Not correct if damping is not proportional and we have closely spaced modes!
